Synthesis and characterization of inorganic-organic hybrid gallium selenides

Sarah J. Ewing[†] and Paz Vaquero^{†‡*}

[†]Institute of Chemical Sciences, Heriot Watt University, Edinburgh, EH14 4AS, UK.

[‡]Present Address: Department of Chemistry, University of Reading, Whiteknights, Reading, RG6 6AD.

Keywords: Solvothermal synthesis, diaminocyclohexane, gallium selenide, inorganic-organic hybrid.

Supporting Information Placeholder

ABSTRACT: Two semiconducting hybrid gallium selenides, $[\text{Ga}_6\text{Se}_9(\text{C}_6\text{H}_{14}\text{N}_2)_4][\text{H}_2\text{O}]$ (1) and $[\text{C}_6\text{H}_{14}\text{N}_2][\text{Ga}_4\text{Se}_6(\text{C}_6\text{H}_{14}\text{N}_2)_2]$ (2), were prepared using a solvothermal method in the presence of 1,2-diaminocyclohexane (1,2-DACH). Both materials consist of neutral inorganic layers, in which 1,2-DACH is covalently bonded to gallium. In (1), the organic amine acts as a monodentate and a bidentate ligand, while in (2) bidentate and uncoordinated 1,2-DACH molecules coexist.

Condensed gallium chalcogenides, prepared by conventional solid-state synthesis, have been the subject of numerous studies, owing to their interesting semiconducting and non-linear optical properties.¹ By contrast, the development of microporous and hybrid gallium chalcogenides, especially selenides and tellurides, is still in its early stages. Solvothermal synthesis has been successfully exploited for the preparation of gallium sulfide and selenide frameworks consisting of corner-linked supertetrahedral clusters.² These framework materials exhibit high surface areas, ion-exchange capacity, and photoluminescence. In the case of gallium sulfides, organic amines can act as linkers between supertetrahedral clusters, leading to the formation of a variety of hybrid one- and three-dimensional covalent networks.³ Supertetrahedral clusters appear to be less prevalent in gallium selenide chemistry, and the formation organically-functionalised tetrahedral clusters has not been reported to date. Moreover, solvothermally-prepared gallium selenides in which amines are covalently bonded to the anionic network are extremely rare, with only one example known, $[\text{enH}][\text{Ga}_4\text{Se}_7(\text{en})_2]$.⁴ Here we report the crystal structure (Table 1) and optical properties of two hybrid gallium selenides, $[\text{Ga}_6\text{Se}_9(\text{C}_6\text{H}_{14}\text{N}_2)_4][\text{H}_2\text{O}]$ (1) and $[\text{C}_6\text{H}_{14}\text{N}_2][\text{Ga}_4\text{Se}_6(\text{C}_6\text{H}_{14}\text{N}_2)_2]$ (2), which were prepared under solvothermal conditions (see Supporting Information), in the presence of 1,2-diaminocyclohexane (1,2-DACH). The ability of this amine to act as a chelating ligand leads to markedly different products to those previously found by us when using the 1,4-diaminocyclohexane isomer.⁵

The crystal structure of $[\text{Ga}_6\text{Se}_9(\text{C}_6\text{H}_{14}\text{N}_2)_4][\text{H}_2\text{O}]$ (1) (Table 1) contains four crystallographically-independent gallium atoms (Figure 1), found in either solely inorganic GaSe_4 tetrahedra, or in hybrid tetrahedra, GaSe_3N and GaSe_2N_2 , in

which 1,2-DACH acts as a monodentate or bidentate ligand respectively. Ga-Se distances range from 2.3148(10) to 2.4233(9) Å which are comparable to Ga-Se distances in gallium selenides in the literature,⁴ whilst Ga-N distances, which range from 2.018(12) to 2.030(6) Å, are significantly shorter than the Ga-Se distances.

Table 1: Crystallographic Data for (1) and (2)

	(1)	(2)
Cryst Syst	Orthorhombic	Monoclinic
Space group	$Pnma$	$P2_1/n$
$a/\text{\AA}$	11.1919(7)	14.2095(8)
$b/\text{\AA}$	19.6774(12)	11.0633(6)
$c/\text{\AA}$	20.8361(13)	21.2998(11)
$\beta/^\circ$	-	105.253(3)
No. Parameters refined	191	211
R_{merg}	0.080	0.054
$R(I > 3\sigma(I))$	0.0369	0.0550
R_w	0.0385	0.0530

Figure 1: Local coordination diagram for (1) showing the atom labeling scheme and ellipsoids at 50% probability.

The structure of (1) contains chains of vertex-sharing tetrahedra, in which GaSe_4 tetrahedra alternate with GaSe_3N and GaSe_2N_2 tetrahedra. Cross-linking of these chains through the terminal selenium atoms results in the for-

mation of layers containing eight- and six-membered rings (Figure 2(a)). These layers, which are neutral, are aligned parallel to the (001) plane, and arranged in a *back-to-back* stacking sequence (Figure 2(b)), with the ligands rotated by *ca.* 90° on opposite sides of consecutive layers.

Figure 2: View of (a) a $[\text{Ga}_6\text{Se}_9(\text{C}_6\text{H}_{14}\text{N}_2)_4]$ layer along $[001]$, and (b) the crystal structure of (1) along $[210]$.

The monodentate 1,2-DACH ligand is disordered over two positions, which correspond to the *cis*- and *trans*-isomers (Figure 1). The *cis*-isomer is dominant with a 65(1)% occupancy compared to 35(1)% for the *trans*-isomer. A water molecule is located inside each eight-membered ring, and the distances between non-coordinating amine groups and water ($\text{N}(13)\text{cis}-\text{O}$ 2.75(4) Å, $\text{N}(15)\text{trans}-\text{O}$ 2.60(3) Å), are consistent with the presence of hydrogen bonding interactions.

The structure of $[\text{C}_6\text{H}_{14}\text{N}_2][\text{Ga}_4\text{Se}_6(\text{C}_6\text{H}_{14}\text{N}_2)_2]$ (2) contains neutral $[\text{Ga}_4\text{Se}_6(\text{C}_6\text{H}_{14}\text{N}_2)_2]$ layers, in which 1,2-DACH acts as a bidentate ligand. These layers are composed of chains of alternating GaSe_4 and GaSe_2N_2 tetrahedra (Figure 3). In these tetrahedra, Ga-Se distances lie over the range 2.3108(13) to 2.4203(11) Å, while Ga-N distances range from 2.016(7) to 2.040(7) Å. These are comparable to values in the literature,⁴ and to those found for (1).

Figure 3: Local coordination diagram for (2) showing the atom labeling scheme and ellipsoids at 50% probability.

Within a given a chain, the GaSe_4 and GaSe_2N_2 tetrahedra are linked by their corners. Additional edge-sharing linkages through the terminal Se(5) and Se(7) create layers, which

contain six- and fourteen-membered rings (Figure 4(a)). The inorganic component of the layer has a sinusoidal-wave shape, while the bidentate 1,2-DACH ligands are oriented towards the outer part of the layers. The layers are stacked in an AB repeating sequence, with additional 1,2-DACH moieties located between the layers. As the layers are neutral, protonation of the uncoordinated 1,2-DACH molecules is not required. Both *cis*- and *trans*- isomers are present in the crystal structure. The interlayer 1,2-DACH is a 51(2):49(2) *cis:trans* mixture, whilst the bidentate 1,2-DACH bonded to Ga(4) is a 41(2):59(2) *cis:trans* mixture. The N-H...Se distances between the non-coordinating 1,2-DACH and the layers (e.g. $\text{N}(27)-\text{Se}(9)$ 3.501(7) Å) imply the presence of hydrogen bonding interactions.

Infrared spectra (Supporting information) of (1) and (2) are consistent with the presence of 1,2-DACH. Stretches at 3138 and 3204 cm^{-1} for (1) and (2) respectively can be assigned to the N-H symmetric stretch of the $-\text{NH}_2$ groups. Peaks at 2962 and 2897 cm^{-1} for (1) and (2) were assigned to C-H stretches. C-N stretching vibrations are observed at 1396 and 1378 cm^{-1} for (1) and (2).

Figure 4: View of (a) a layer of (2) along $[301]$, and (b) the crystal structure of (2) along $[010]$.

Thermogravimetric analysis (TGA) (Supporting information) under an oxidising atmosphere shows that (1) and (2) are stable up to *ca.* 150°C and 200°C respectively. Decomposition of the materials occurs in two steps. A ~20% weight loss is observed for the initial decomposition step of (1). This loss could be attributed to the loss of water and monodentate 1,2-DACH (calculated loss of 15.5%). The overall weight loss is 65.1%, in excellent agreement with the calculated weight loss of 64.9% for the decomposition of (1) to Ga_2O_3 . The first decomposition step of (2), 26.2%, can be attributed to the loss of the 1,2-DACH moieties (calc. 31.3%). Total loss of 59.9% is in reasonable agreement with the decomposition of $[\text{C}_6\text{H}_{14}\text{N}_2][\text{Ga}_4\text{Se}_6(\text{C}_6\text{H}_{14}\text{N}_2)_2]$ to Ga_2O_3 (calc. 65.8%).

The UV-vis optical absorption spectra of (1) and (2) are shown in Figure 5. The estimated band gaps are 2.36(2) eV for compound (1) and 2.30(6) eV for (2), larger than those found for the bulk selenides Ga_2Se_3 (2.1 eV) and GaSe (1.97 eV).⁶ For solvothermally-prepared antimony sulphides, it has been found that an increase in framework density leads to a decrease in the optical band gap.⁷ This correlation also seems to hold here, given that (1) and (2) have larger band gaps than the corresponding condensed phases. This is consistent with DFT calculations on a related layered hybrid selenide, $[\text{CdSe}(\text{hda})_{0.5}]$ (hda = 1,6-hexanediamine), which show that the electronic band-edge states are dominated by the inor-

ganic layers, and that the conduction and valence bands are narrower than in bulk CdSe, resulting in a larger band gap.⁸

Figure 5: Optical absorption spectra of (1) (black line) and (2) (red line).

An unusual feature of (1) and (2) is the presence of an organic amine covalently bonded to a main-group metal centre. In solvothermally-prepared main-group chalcogenides, the organic amines are normally incorporated into the crystal structure as counteranions, and bonded through electrostatic and weak hydrogen bonding interactions.⁹ Gallium however has a higher acid character than other main-group elements, and this favours bonding with hard bases, in this case the organic amine. Covalently-bonded amines have been previously found in gallium sulfides³ and in $[\text{enH}][\text{Ga}_4\text{Se}_7(\text{en})_2]$.⁴ In the heavier tellurides, amines have been found to form covalent bonds to indium, as exemplified by $[\text{M}(\text{phen})_3]_2[\text{In}_8\text{Te}_{30}(\text{dapn})_6] \cdot 2\text{Hdapn} \cdot \text{dapn}$ ($\text{M} = \text{Fe}(\text{II})$, and $\text{Ni}(\text{II})$, $\text{dapn} = 1,3\text{-diaminepropane}$),¹⁰ $[\text{Mn}(\text{DACH})_3]_2[\text{In}_8\text{Te}_{30}(\text{DACH})_6][\text{DACHH}_2][\text{H}_2\text{O}]$ ¹¹ and $[\text{In}(\text{en})_3][\text{In}_5\text{Te}_8(\text{en})_2] \cdot 0.5\text{en}$.¹² This suggests that for Group 13 elements, the relative stabilities of the metal-chalcogen and metal-nitrogen bonds under solvothermal conditions are finely balanced.

The hybrid gallium selenides reported here can be considered to be related to the family of II/VI hybrid semiconductors, which have the general formula $[\text{MQ}(\text{L})_x]$ ($\text{M} = \text{Mn}, \text{Zn}, \text{Cd}$; $\text{Q} = \text{S}, \text{Se}, \text{Te}$; $\text{L} = \text{organic amine}$), and consist of inorganic slabs sandwiched by covalently-bonded organic layers.¹³ These hybrid materials have been found to exhibit remarkable properties, including large band-gap tunability,¹³ broad photoluminescent emission which can result in direct white light emission^{13(c),(e)} and zero thermal expansion.^{13(b)} The inorganic slabs of the $[\text{MQ}(\text{L})_x]$ phases retain the connectivity of the zinc blende or the wurtzite structures found in bulk II/VI semiconductors, and consist of corner-sharing MQ_4 and MQ_3N tetrahedra. By contrast, the inorganic layers in (1) and (2) are not related to the defect zinc blende structure of Ga_2Se_3 , and contain GaSe_4 , GaSe_3N and GaSe_2N_2 tetrahedra, which can be vertex- or edged-linked. However, in common with $[\text{MQ}(\text{L})_x]$ phases, the layers in (1) and (2) are neutral, and held together by weak van der Waals or hydrogen bonding interactions. It has been shown that exfoliation of $[\text{MQ}(\text{L})_x]$ phases is possible, and results in the creation of freestanding single layers,¹⁴ which can be considered inorganic graphene analogues. We envisage that exfoliation of (1) and (2) may also be feasible. Our current efforts with hybrid gallium selenides are directed towards the synthesis of addi-

tional members of this family and the detailed investigation of their optical properties.
